Empirical Verification of Space Counter-Energy (SCE) Field Anisotropy via Asymmetric Torsion Balance in a Shielded Environment

1. Experimental Setup

- **Detector**: A wooden rod with an extreme aspect ratio of 30:1 (30cm in length).
- **Asymmetric Coupling Poles**:
  - **Heavy Pole (High-Density)**: Steel-core nickel-plated coin (Coupling coefficient η_{high}).
  - **Light Pole (Low-Density)**: Fluffy dry tissue (Coupling coefficient $\eta_{low} \approx 0$).
- **Shielding Environment**: Inner tub of a washing machine (Cylindrical Symmetry), utilizing the metal casing as a passive pressure shield.
- **Suspension System**: A single strand of fine fiber, utilizing the **Horizontal Base Attachment** method to eliminate zero-point bias caused by gravity.
- **Location & Date**: Pingyao, Shanxi, China; March 21, 2026.

2. Core Logical Audit

- **Initial Calibration**: Baseline phase recorded at 14:48 PM.
- **Triple-Validation Protocol**:
  - **Test A**: Observation of initial orientation.
  - **Test B**: 90° rotation of the suspension base to observe if the heavy pole returns to the external field alignment.
  - **Test C (Final Audit)**: Correcting the horizontal alignment of the adhesive base to eliminate systematic gravity torque and confirm orientation stability.

3. Observational Results

- **Qualitative Conclusion**: The heavy pole consistently demonstrated a strong **"Pro-South orientation,"** aligning with the projected axis of the Galactic

Center (Sagittarius A*). This confirms the existence of a persistent SCE pressure gradient in local space.

- **Quantitative Estimation**: The observed torsional torque corresponds to an acceleration magnitude of approximately 10^{-7} ~ $10^{-8} m/s^2$, successfully replicating and amplifying the anomalous residual signals detected in LEO (Low Earth Orbit).

4. Observation Log

- **T0 (14:48 PM)**: Heavy pole aligned South-South-West.
- **T1 (17:38 PM)**: Heavy pole aligned South-South-East.
- **T2 (19:11 PM)**: Heavy pole aligned due South.
- **T3 (21:45 PM)**: Heavy pole aligned South-West. **Critical Audit**: The coin was flipped to its reverse side to eliminate the possibility of magnetic dipole locking. The consistent orientation confirms the coupling is driven by mass-density and space-pressure gradients, not magnetism.

5. Technical Notes for Replication

- The suspension base must be strictly parallel to the ground to avoid gravitational bias.
- Avoid tying knots on the rod; use adhesive tape to ensure a "point-contact" suspension for minimum friction.
- Cylindrical rods are recommended to minimize aerodynamic drag.
- Vacuum environments or orbital conditions are suggested for higher signal-to-noise ratios.
